### I. PROBLEM STATEMENT

Given the transformation law for the metric:

$$\delta g_{ab} = -\partial_a v_b - \partial_b v_a \quad (1)$$

determine the most general  $v^a(\sigma)$  that leaves flat  $d$ -dimensional Euclidian metric  $\delta_{ab}$  invariant up to a local rescaling.

### II. SOLUTION

The case of  $d = 2$  is covered extensively in String Theory textbooks, so we will concentrate our efforts on  $d > 2$  here.

#### A. Notation

Everywhere below  $a, b$ , and  $c$  are three different indices:  $a \neq b, b \neq c, a \neq c$ . Note that it means that most of the derivation does not apply to  $d = 2$ . This the reason why  $d = 2$  is special.

$m$  and  $n$  are possibly equal, but both non-negative integers:  $m \geq 0, n \geq 0$ .

#### B. Derivation

The local rescaling invariance imposes following constraints:

$$\partial_a v_a = \partial_b v_b, \quad (2)$$

$$\partial_b v_a = -\partial_a v_b. \quad (3)$$

For  $d > 2$  we can derive an additional constraint:

$$\begin{aligned} \partial_c (\partial_b v_a) &= -\partial_c (\partial_a v_b) = -\partial_a (\partial_c v_b) = \\ \partial_a \partial_b v_c &= \partial_b (\partial_a v_c), \end{aligned} \quad (4)$$

which is equivalent to:

$$\partial_b (\partial_c v_a - \partial_a v_c) = 2\partial_b \partial_c v_a = 0. \quad (5)$$

This immediately implies that  $v_a$  can't have terms with three different coordinate variables:

$$v_a = \sum_{\substack{m \geq 0, n \geq 0 \\ b \neq a}} c_{mn}^{(ab)} (\sigma_a)^m (\sigma_b)^n, \quad (6)$$

$$c_{m0}^{(ab)} = c_{m0}^{(ac)}. \quad (7)$$

In fact, the space of solutions is even smaller. The term

$$v_a = (\sigma_a)^{m+2} (\sigma_b)^{n+1} + \dots \quad (8)$$

is incompatible with constraints:

$$\partial_c v_c = \partial_a v_a = (m+2)(\sigma_a)^{m+1} (\sigma_b)^{n+1}, \quad (9)$$

but  $v_c$  can't have a term proportional to  $(\sigma_c)(\sigma_a)^{m+1}(\sigma_b)^{n+1}$  due to (5). Therefore

$$c_{(m+2)(n+1)}^{(ab)} = 0. \quad (10)$$

As we shall see only finitely few of them are non-zero, and even less are independent of each other.

The first constraint (2) can be translated from differential equation

$$\partial_a v_a = \sum m c_{mn}^{(ab)} (\sigma_a)^{m-1} (\sigma_b)^n \quad (11)$$

$$= \partial_b v_b = \sum n c_{nm}^{(ba)} (\sigma_b)^{n-1} (\sigma_a)^m \quad (12)$$

to a relation between coefficients

$$(m+1)c_{(m+1)n}^{(ab)} = (n+1)c_{(n+1)m}^{(ba)}. \quad (13)$$

Similarly (3) translates to

$$(n+1)c_{m(n+1)}^{(ab)} = -(m+1)c_{n(m+1)}^{(ba)}. \quad (14)$$

Combining (13) and (14) together we see that

$$c_{(m+2)n}^{(ab)} = -\frac{(n+2)(n+1)}{(m+2)(m+1)} c_{m(n+2)}^{(ab)}, \quad (15)$$

which together with (10) implies that

$$c_{m(n+3)}^{(ab)} \simeq c_{(m+2)(n+1)}^{(ab)} = 0, \quad (16)$$

$$c_{(m+4)n}^{(ab)} \simeq c_{(m+2)(n+2)}^{(ab)} = 0. \quad (17)$$

Therefore the only coefficients that can be non-zero are

$$c^{(a)} \equiv c_{00}^{(ab)}, \quad c_1^{(a)} \equiv c_{10}^{(ab)}, \quad c_{01}^{(ab)}, \quad (18)$$

$$c_{11}^{(ab)}, \quad c_{12}^{(ab)}, \quad c_3^{(a)} \equiv c_{30}^{(ab)}. \quad (19)$$

We can also work out relations between them. Using (13) and (14):

$$c_1^{(a)} = c_{10}^{(ab)} = c_{10}^{(ba)} = c_1^{(b)}, \quad (20)$$

$$c_{01}^{(ab)} = -c_{01}^{(ba)}, \quad (21)$$

$$c_{11}^{(ab)} = -2c_{02}^{(ba)} = 2c_{20}^{(ba)} = 2c_2^{(b)}, \quad (22)$$

$$c_3^{(a)} = c_{30}^{(ab)} = \frac{1}{3}c_{12}^{(ba)} = -\frac{1}{3}c_{12}^{(ab)} = -c_{30}^{(ba)} = -c_3^{(b)}, \quad (23)$$

but the (23) has to be zero

$$c_3^{(a)} = -c_3^{(b)} = c_3^{(c)} = -c_3^{(a)} = 0. \quad (24)$$

Before writing out the most general form of  $v^a$ , let us count the number of independent solutions

$$\# \left\{ c^{(a)} \right\} = d, \quad (25)$$

$$\# \left\{ c_1^{(a)} = c_1^{(b)} \right\} = 1, \quad (26)$$

$$\# \left\{ c_{01}^{(ab)} = -c_{01}^{(ba)} \right\} = \frac{d(d-1)}{2}, \quad (27)$$

$$\# \left\{ c_2^{(a)} \right\} = d, \quad (28)$$

and the total

$$d + 1 + \frac{d(d-1)}{2} + d \quad (29)$$

$$= \frac{2d + 2 + d^2 - d + 2d}{2} \quad (30)$$

$$= \frac{d^2 + 3d + 2}{2} \quad (31)$$

$$= \frac{(d+1)(d+2)}{2}. \quad (32)$$

### C. Result

The most general form of solution is:

$$\begin{aligned} v^a = & c_0 + c_1(\sigma_a) + c_2(\sigma_a)^2 \\ & + \sum_b [c_3(\sigma_a)(\sigma_b) + -2c_4(\sigma_b)^2] \\ & + \sum_b c_5 \left[ (\sigma_a)^3 - \frac{1}{3}(\sigma_a)(\sigma_b)^2 \right]. \end{aligned} \quad (33)$$
